R/RStudio - First Steps:: CHEAT SHEET

Basic Workflow Tips

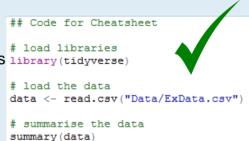

How to treat datafiles

Leave your original data set unchanged. In this way you cannot make any changes that cannot be reversed!

Raw data are read-only!

Instead we write commands/code in R which instructs R to import the data and make any changes library (tidyverse) and calculations required. This makes your work reproducible! These files are called script # summarise the data

NEVER WRITE OVER YOUR ORIGINAL DATAFILE

Save your work and make it reproducible

The way to work in R is by using scripts. These are files in which you collect all the actions you perform on the data (data cleaning, summary stats, graphing,

This is a record of your work which you can pass on to others but also makes it easy to re-run the analysis, e.g. after fixing a mistake or after obtaining additional data.

Commenting

3 ₹	# load libraries
4	library(tidyverse)
5	library(ggplot2)
6	
7 +	# Data Upload
8	data <- read.csv("Data/ExData.csv")
9	
10 +	# Data Summary
11	summary(data) # summary stats

Everything after a "#" is a comment and only used to help you and others understand what the code intends

By creating a comment line ending in "----" you create a "sort of chapter" in your code. Collapse a chapter by clicking on the little triangle on the left of that line.

Test your code as frequently as possible

When you write code make sure that you test every line of code straight after writing it. As you develop your code you will encounter many mistakes and if you wrote many lines of code without testing, then it may be difficult to figure out which line is faulty.

The RStudio Layout

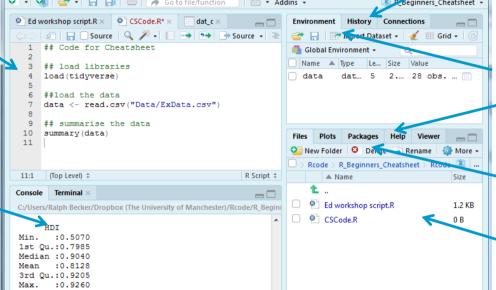

CODE EDITOR

In this window you will see your code/script files. This is where you record what you want to do.

CONSOLE

Here you will see any output produced by your code. You can also enter individual commands to either test them before you include them into your script or because you are not planning to include these in your script.

HISTORY

In this tab you can find a history of the commands you used.

ENVIRONMENT

Here you can see all objects/variables that have been loaded or created by your code.

Help

Shows help files if you type "?read.csv" i(or any other function name) into the console.

PACKAGES

In this tab you manage (install, update) your packages.

FILES

The files and folders in your working directory appear here.

File Management

Folders

Make sure you know where your files are. It is advisable to create a folder into which you save all files that you use for a particular project. If your project has many files you should consider creating sensible subfolders for code, data, images. documentation or any other category of data.

Working Directory

You should let R know what directory you are working off. # set working directory setwd("YOUR DIRECTORY")

We call this the working directory and you set it with the "setwd" command. Put the full file path inbetween the quotation marks.

RStudio Project files

You should consider using RStudio project files. This will facilitate file management and make references to data and other files more straightforward. Help on how to use them is available from RStudio or Softwarecarpentry.

This is particularly useful if you want to share your work with others.

Useful RStudio Shortcuts

What	Icon	Windows	Mac
Save script		CTRL+S	COMMAND+S
Run entire script	→ Source →	CTRL+ SHIFT+S	COMMAND+ SHIFT+S
Run current line/selection	□→ Run	CTRL+ ENTER	COMMAND+ ENTER
Clear Console		CTRL+L	CPMMAND+L
Undo		CTRL+Z	COMMAND+Z
Re-indent		CTRL+I	COMMAND+I
Clear Workspace	1		
Piping operator. %>%		CTRL+ SHIFT+M	COMMAND+ SHIFT+M

R/RStudio – First Steps:: CHEAT SHEET

Packages

R is an open source software which has a lot of functionality build-in. However, a lot of very useful additional functions are provided by extra packages. TO be able to use these you need to:

- 1. Find the package you need (Google or check out <u>CRAN</u> <u>Task view</u> for starters).
- 2. The package needs to be installed on the machine you are using. Run install.packages("PACKAGENAME")
 (quotation marks need to be included) or use the interactive function in the packages tab:

3. In the script in which you use a function which is provided by a package you need to load that package by running the following line in your script:

library (PACKAGENAME) or library ("PACKAGENAME")

Some useful packages

Package	What it does
tidyverse	This is the swiss army-knife for the R-analyst; helps with most data tasks
readxl	This will support the import of Excel spreadsheets
ggplot2	Creates amazing plots
rmarkdown	Allows you to create Rmarkdown documents which produce excellent documents that mix code, output and text.
forecast	Provides a lot of time-series functionality
car	A package with plenty of functions for regression analysis

BOOLEAN VARIABLES

> a <- 3
> (a < 4)
[1] TRUE
> (a == 5)
[1] FALSE
> (a == 5) (a < 4)
[1] TRUE

Variables which take TRUE or FALSE as values. You can assign the result to a new variable. These variables have many uses. Combine conditions with "&" (and) or "|" (or).

Basic data management

library(tidyverse, readxl, car)

IMPORT DATA (from csv or excel)

```
dat_c <- read.csv("Data/ExData.csv") # from csv
dat_c <- read_excel("Data/ExData.xlsx", sheet="Sheet1")</pre>
```

EXAMINE DATA

FIND MISSING DATA

Finds missing values. Creates TRUE/FALSE (Boolean) variable. dat_comp contains only complete observations

is.na(dat_c)
dat_comp <- dat_c %>% drop_na()

FILTER / SUBSET DATA (by one or more criteria)

```
dat_c %>% filter(Country == "Canada", Year==2011)
```

SORT DATA (by the values of a variable)

If you want to order from largest to lowest use desc()

dat_c %>% arrange(desc(HDI))

CREATE NEW DATAFRAME

You can combine several of the above actions and create a new dataframe, data_sel.

```
data_sel <- dat_c %>% filter(Year == 2011)
%>% arrange(Country)
```

CREATE A NEW OR CHANGE AN EXISTING VARIABLE

```
dat_c <- dat_c %>%
  mutate(co2int = CO2emission.pp/Income.pp)
```

0.000149

0.000106

3 Denmark

4 Nigeria

GROUP DATA AND CALCUATE SUMMARY STATS

```
dat_c %>% group_by(Country) %>%
summarise(mean.CO2int=mean(co2int,na.rm = TRUE)) %>%
arrange(desc(mean.CO2int))

Country mean.CO2int
1 South Korea 0.000365
2 Canada 0.000357

In South Korea and Canada, income is produced with much
```

more CO2 emissions than in

Denmark and Nigeria.

Error Management

When writing code you will encounter problems and error messages. This happened to everyone and is a normal part of code writing.

R Studio

When you encounter an issue do this first:

- 1. Re-read what you typed, is it 'exactly' what you wanted? (R is case sensitive! Don't use spaces in variable names!)
- 2. Re-run code one line at a time and identify line with error.
- 3. Read error message and try to find anything that you can understand. Don't worry about the parts you don't understand there will be lots!

Common error messages

- 'No such file or directory' R cannot find the file, Check the file really exists in the specified folder. This could be because it is looking in the wrong place or you have mistyped. Check getwd() to see what R's working directory is. Use setwd("yourdir") to change working directory.
- 'Error: object 'name' not found' R cannot find the object `name`. This could be because you've mistyped, because you need quotes around the name or because you are referring to a variable that does not yet exist.
- 'Could not find function "name" R cannot find the function.
 This could be because you've mistyped or because you haven't used library() to load the package containing that function.

Searching for help

Possibly the most important programming skill (and everyone does it!). Either google an error code or a question you have (e.g. "R delete variable from dataframe"). You may have to look at a number of the first links to find useful info. Many links will be from "stackoverflow.com". Posts on here can be very useful. You may need to copy some code and try to adjust it to your problem at hand.

Also don't forget to use the R help function. E.g. type ?1m into the Console to get help on using the regression function. Start solving your problem step-by-step, meaning that you try to create the smallest possible problem first before you make your problem more complicated.

REGRESSION

lm is the function to run a regression, summary prints the
results and lht can be used to test simple or multiple
hypotheses

```
reg1 <- lm(Income.pp~CO2emission.pp,data = dat_c)
summary(reg1)
lht(reg1, "CO2emission.pp = 1000")</pre>
```
